79 1 **INTRODUCTION**

80

81 1.1 **Background and objectives**

82

83 The Smart Meter Coordination Group (SM-CG) published a Technical Report (TR):
84 “Functional reference architecture for communications in Smart Metering Systems”
85 (CEN/CLC/ETSI TR 50572, reference [1]) that comprises a reference architecture, an
86 overview of communication standards and the work programs of the European Standards
87 Organizations (ESOs) regarding these standards.

88

89 Although the standards needed for interoperability of components of the Advanced Metering
90 Infrastructure are dealt with in TR 50572, the privacy of consumer owned data and the
91 security of transactions and data access within the AMI need further attention, given their
92 importance to many stakeholders involved in or influenced by the implementation of Smart
93 Meters.

94

95 In the SM-CG plenary meeting on 27 June 2012 it was decided that a new chapter about the
96 approach of the ESOs regarding Privacy and Security should be included in the SM-CG
97 deliverables. A Task Force was formed to define such an approach and give insight in the
98 work planned by the Technical Committees to address privacy and security. The Privacy &
99 Security Task Force produced a first report (Part I) in November 2012 that was finally
100 released in February 2013.

101

102 This document represents the results of the additional work initiated in June 2012. It
103 comprises:

- 104 - an approach to define requirements for privacy and security standards
- 105 - a repository of privacy and security requirements
- 106 - the application of the European Data Protection Impact Assessment (DPIA) template to
107 smart metering
- 108 - a description of the present status of standardisation work by the SM-CG Coordinating
109 Technical Committees, related to privacy and security
- 110 - a comparison of available security certification schemes

111

112 The repository of privacy and security requirements forms a basis for:

- 113 - Evaluating standards regarding their compliance with these requirements

SM-CG Sec073_DC

- 114 - Enhancing the Technical Requirements defined by the SM-CG (see reference [4])
115 that are used to be linked to Use Case steps (see reference [3]).

116

117 1.2 Scope

118

119 The scope of the work of the Task Force is privacy and security within the boundaries of the
120 functional reference architecture defined in TR 50572 shown below. The approach of the
121 Privacy and Security Task Force in standardisation and the current work of the TCs will focus
122 on the interfaces as shown in this figure.

123

124 However, even though the particular architecture being implemented by a member state may
125 respect the M/441 generic reference model, when considering P&S solutions in practice it is
126 essential to take account of all the factors associated with the metering infrastructure
127 concerned (gas, electricity, water or heat), including the specific architecture being adopted
128 by the member state concerned, the nature of the data involved and any differences of
129 approach which may be necessitated by the very different characteristics of battery and
130 mains powered meters.

131

132 Although privacy and security issues are related, they require separate consideration. Whilst
133 privacy cannot be assured without adequate security measures, ensuring security will not be
134 sufficient to guarantee privacy.

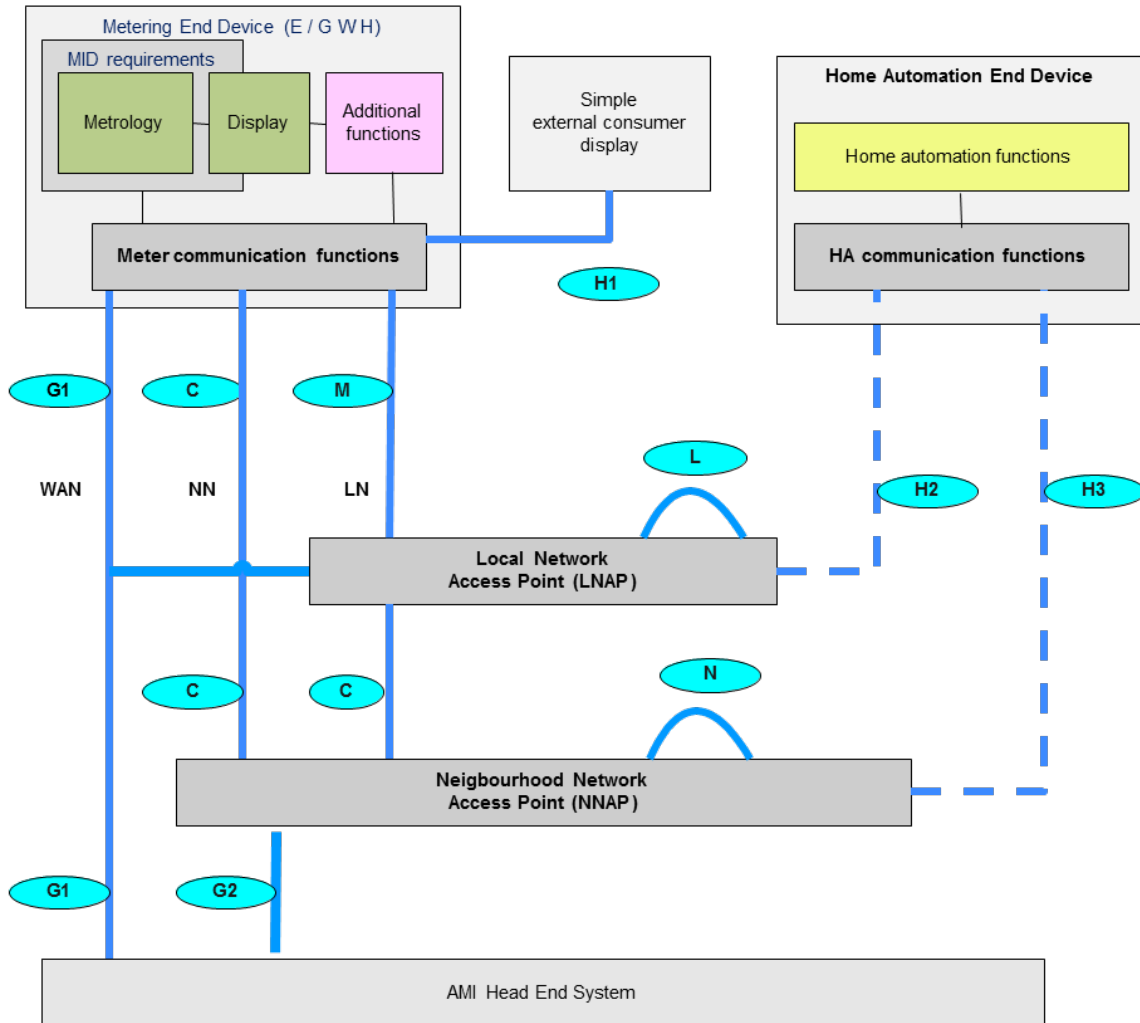

Figure 1 – The SM-CG functional reference model

135
136
137

138 2 **THE APPROACH TO DEFINING REQUIREMENTS FOR**
139 **STANDARDS**
140

141 2.1 **Introduction**
142

143 In 2012 the Smart Grid Information Security (SGIS) working group of the Smart Grid
144 Coordination Group (SG-CG) provided a methodology to help define security requirements
145 through a Use Case based approach. The process of defining or selecting security
146 requirements was described in Part I of the Privacy & Security Task Force report (reference
147 [2]).
148

149 A similar approach has been adopted by Expert Group 2 of the EU Smart Grid Task Force.
150 This EG, responsible for *Regulatory Recommendations for Data Privacy and Data Protection*
151 *in the Smart Grid Environment*, has produced a Data Protection Impact Assessment
152 template, which is also based on use cases and uses risk analysis to help identify measures
153 necessary for risk mitigation. This DPIA (reference [5]) has been used as input for this Part II
154 report to provide an approach for defining or selecting privacy requirements for Smart
155 Metering.
156

157 At workshops in July & November 2013 the SM-CG Privacy & Security Task Force, together
158 with members of EG2 and the SG-CG, applied the DPIA template to one of the SM-CG use
159 cases in order to evaluate and improve the approach as regards smart metering. The results
160 of this workshop have been incorporated in the recommendations in this report.
161

162 2.2 **Definition of Privacy and Security requirements**
163

164 2.2.1 **The Smart Grid Information Security Group (SGIS) in 2013**
165

166 Currently the SGIS is working with sub teams and each sub team (Work Package) produces
167 its own report.
168

169 A single report comprising 4 issues: standards selection, security recommendations, privacy
170 considerations and toolbox application is expected by the yearend 2013.
171

WP1 – SGIS Set of Standards

A draft report for Smart Grid Set of Security Standards has been compiled and circulated within the sub team. Currently addressed standards in terms of overview description, mapping to the SG-CG Smart Grid Architecture Model (SGAM), and gap identification in the report are:

- IEC 62351
- IEC 62443-2-4, IEC 62443-3-3, IEC 62443-4-2
- ISO/IEC 15408 + ISO/IEC 18045

Further investigation into selected standards and potential gaps, based on selected use cases, is due by the end of the year 2013.

188 **WP2 – Cyber security**

189

190 *WP2.1 – European Set of Recommendations*

191 Security recommendations from ENISA, NERC CIP, NISTIR 7628, SM-CG and other team
192 inputs are presented in a final report, which is due mid-December 2013. These proposed
193 recommendations are mapped to the Smart Grid Architecture Model (SGAM).

194

195 *WP2.2 – Applied Information Security on Smart Grid Use Cases*

196 The SGIS Toolbox v2 (see reference [2] for a description) is applied on Smart Grid Use
197 Cases that are clustered in 3 groups: Substation Automation, DER, and Electric Vehicles.
198 The following deliverables per Use Case will be available: Use Case summary, mapping to
199 the Smart Grid Architecture Model (SGAM), ad hoc recommendations based on Toolbox
200 usage.

201

202 **WP3 – Privacy**

203

204 *WP3.1 – Analyse Effect of proposed Data Protection Regulation*

205 The current Data Protection regulatory framework is compared with the potential new regime
206 on EU and national level. More specifically, data privacy regulation is reviewed in four
207 Member states. Currently a draft outline document with a first analysis of the market
208 overview has been made. The final report on National Data Privacy Regulation is due at the
209 end of January 2014.

210

211 *WP3.2 – Impact assessment of Use Cases in four Member states*

212 In two workshops the Data Protection Impact Analysis (DPIA) template developed by EG2 of
213 the Task Force Smart Grids (see 2.2.3) has been applied to specific Smart Metering Use
214 Cases (developed by the SM-CG, see reference [3]) in 2013. The regulation, deployments
215 and market structure of Germany and France were reviewed in detail, and this work was
216 informed by input from the UK and The Netherlands. The results and recommendations from
217 these workshops are intended to lead to the development of an improved approach to data
218 protection within the SGIS toolbox in 2014.

219

220

221

222

223 *WP3.3 – Analysis of existing and emerging conceptual and technological solutions*

224 In 2013 the WP group has identified potential concepts, technological solutions and
225 described and analyzed potential mitigation solutions. In January 2014 the development of
226 the final report will commence.

227

228 *WP3.4 – Integration and dissemination to other groups*

229 Throughout 2013 links to EG2 DPIA, Security Levels, Toolbox, European institutions, USA
230 (NIST) and other stakeholders were established. Moreover, a new link to SM-CG AHWG
231 Privacy & Security was introduced in 2013 during a workshop meeting with SMCG, EG2 and
232 WP3 to perform a DPIA on Smart Metering Use Cases.

233

234 **WP4 – SGIS Toolbox**

235 See following section 2.2.2.

236

237 2.2.2 **The SGIS toolbox**

238

239 *Version 1*

240 Part I of this document (reference [2]) describes version 1 of the SGIS toolbox in detail.

241

242 *Version 2 (2013)*

243 SGIS Toolbox v2 update covers the comments received in 2012 and provides additional
244 elements of likelihood analysis. It includes following major changes:

- 245 • Updated scope & objectives
- 246 • Clear indication of which aspects of risk analysis are covered by v2 of the toolbox and
247 which are for v3
- 248 • Update of risk impact categories
- 249 • Included an asset list to assist with likelihood analysis
- 250 • Included an overview of threat scenarios to assist with likelihood analysis

251

252 This version of the toolbox describes in more detail how to assess use cases, lists the
253 relevant assets categories and identifies a model for determining the Risk Impact Level (RIL)
254 of specific information assets¹ in a use case.

¹ Definition : *An Information Asset is a definable piece of information, stored in any manner which is recognized as 'valuable' to the organization*

255
256
257

The following picture summarizes how the present toolbox is intended to be applied:

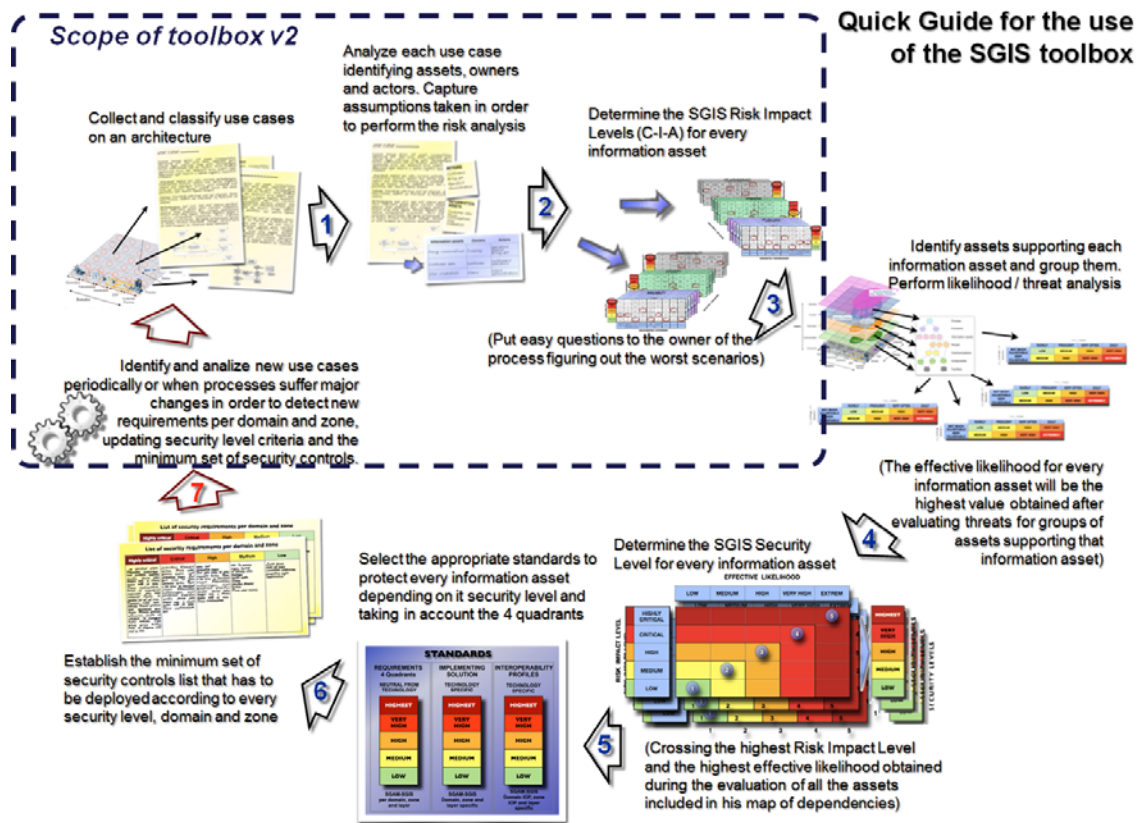

Figure 3 – SGIS toolbox v2.0

258
259
260
261
262
263
264
265
266
267
268
269
270
271

The process starts with collecting and analyzing use cases by identifying activities and assets. Based on this description of the functionality, the assets and the operational environment, the approach continues with determining the risk impact level for every information asset.

In the next step of the process the user assesses the likelihood of threats. At this stage of the toolbox, this assessment is based on general user experience. Currently, the toolbox does not contain a model for likelihood assessment. It does however contain a number of elements that may assist the user in the likelihood assessment like, for example:

- an asset list
- a dependencies map

- 272
- threat scenario's based on the UK IS1 method

273 The risk impact combined with the likelihood of a threat occurring to an asset results in a
274 notion of inherent risks.

275

276 *Version 3 (2014)*

277 SGIS Toolbox v2 is an intermediary step towards a pragmatic risk analysis approach for
278 smart grids. Version 2 already describes elements of how to build a dependencies map for
279 supporting assets, how to perform a threat and likelihood analysis and how to combine
280 impact and likelihood to get the inherent risk as a result.

281

282 These "loose" elements will be expanded upon in a consistent threat analysis approach in
283 the next version 3 of the SGIS toolbox, which is planned for Q2 2014. Version 3 will also
284 consider other risk assessment methods and a likelihood assessment model for privacy
285 risks. In the end SGIS Security Levels as countermeasures should lead to appropriate
286 security standards.

287

288 As explained in part I of this document (reference [2]), the SGIS toolbox leads to a final
289 selection of privacy and security control/requirements out of a reference list. A reference list
290 for Smart Metering has been included in this document (see chapter 3).

291

292 2.2.3 **Smart Grid Task Force Expert Group 2**

293

294 Expert Group of the EU Task Force Smart Grids was working on three deliverables in 2013.

295

- 296
1. Data Protection Impact Assessment (DPIA): Subsequent to the request in
297 Commission Recommendation 2012/148/EU of 9 March 2012 to develop a DPIA
298 template and to submit it to Article 29 Data Protection Working Party (WP29) for
299 opinion, EG2 was tasked to develop this template. After issuing a draft version early
300 2013, several improvements were suggested resulting in among others: (i)
301 introduction of a risk assessment methodology; (ii) a revised list of Energy
302 stakeholders; (iii) a new clarified list of threats and corresponding controls. EG2
303 submitted a final version to WP29 in August. Subject to WP29's opinion, the
304 Commission may consider the adoption of the DPIA Template in the form of a
305 Commission Recommendation.

306

- 307 2. Best Available Techniques (BATs): Commission Recommendation 2012/148/EU of 9
308 March 2012 on preparations for the roll-out of smart metering systems asked for the
309 development of a set of BATs. They focus on the security risks involved with the
310 Commission's common minimum functional requirements for electricity smart
311 metering and identify controls to mitigate these risks. As an additional source for the
312 ad-hoc selection of best available techniques, a set of BATs is being drafted by EG2,
313 with information collected via (i) a questionnaire; (ii) contact points within the
314 organisations and (iii) projects for smart metering system roll-out listed in the JRC
315 inventory.
316
- 317 3. Minimum security measures: This activity is chaired by ENISA, with the support of EC
318 and is based on ENISA's report which identifies minimum measures for security and
319 resilience for the smart grid service providers and completes the Best Available
320 Techniques which focus merely on Smart Metering. The objective is to organize
321 consultations, collect feedback on these measures from relevant stakeholders, to
322 draft minimum requirements. The Commission might consider adopting a
323 Recommendation on minimum cyber security requirements for Smart Grids which
324 could be issued in 2014.
325

326 2.2.4 EG2 DPIA template

327

328 Background : The Data Protection Impact Assessment, developed and published by EG2²,
329 comprises eight steps:

331 *Step 1 - Pre-assessment and criteria determining the need to conduct a DPIA*

332 In this step the answers on various questions will identify the need to conduct a DPIA:

333 Criterion 1: Is personal data involved?

334 Criterion 2: Is the concerning party a data controller or data processor?

335 Criterion 3: Is there a specific risk to the individual (article 33)?

336 Criterion 4: Is it the right time?

337 Criterion 5: What is the nature of the system/application under review?

338 Criterion 6: Is there a legal basis for the envisaged data processing operations?
339

² Expert Group 2 ('EG2') of the EC Smart Grid Task Force ('SGTF')

340 *Step 2 - Initiation*

341 In this step the basics for conducting the DPIA are arranged:

- 342 • Motivation (see step 1)
- 343 • Budget
- 344 • Human resources
- 345 • Support of senior management

346

347 *Step 3 - Identification, characterization and description of Smart Grid systems / applications*
348 *processing personal data*

349 Now the system architecture and its components (assets) are described. A distinction is
350 made between primary assets (processes and personal data elements) and supporting
351 assets (hardware, software, networks, etc.). Use Cases are created describing the data
352 exchange among the actors and system components.

353

354 *Step 4 - Identification of relevant risks*

355 As with the SGIS toolbox, also the DPIA describes a risk analysis. This step will deliver a list
356 of threats that might influence the system and/or its processes.

357

358 *Step 5 - Data protection risk assessment*

359 Following the threats and feared events, a quantification of severity level and likelihood will
360 result in risk levels related to the threats.

361

362 *Step 6 - Identification and Recommendation of controls and residual risks*

363 For all the risks identified in the assessment, a treatment will be defined (e.g. modification,
364 retention, avoidance, sharing, etc.). The treatments (controls) should lower the likelihood
365 and/or severity of a risk. Accepted residual risks have to be clearly described, so
366 stakeholders understand the risks that are remaining and can be accepted.

367

368 *Step 7 - Documentation and drafting of the DPIA Report*

369

370 *Step 8 - Reviewing and maintenance*

371 Since threats are changing over time, it is important to keep a process in place to monitor the
372 threats and related risks and change or define new controls if needed.

373

374 2.2.5 **Identifying requirements for standards and final implementations**
375

376 The methods in the former sections show how Use Cases can be used to identify the
377 appropriate Privacy and Security controls/requirements. However, since system architectures
378 and Use Cases may differ per Member State or even within Member States, a final Risk
379 Analysis and definition of requirements can only be done when the ICT architecture and
380 functionalities are fixed. Member states can use the method described and Generic Use
381 Cases to finalise their Use Cases and requirements.
382

383 The Generic Use Cases and the reference list of requirements will be maintained by one or
384 more horizontal Technical Committees, so the latest technical and functional developments
385 will be taken in account and the material is updated.
386

387 Although they are of generic nature, the Privacy and Security (P&S) requirements identified
388 by the SM-CG Task Force (see chapter 3) are input for the ESOs to check if their standards
389 can meet these generic requirements. It is therefore recommended by the Task Force that
390 the relevant Technical Committees take these requirements as input for their work and select
391 which of these apply to their scope.
392

393 When selecting and defining P&S requirements it is important to take notice of the
394 differences between architectures and products used in the scope of the M/441 mandate and
395 the technical and economic feasibility and consequences of implementation. For example
396 certain requirements can be unrealistic for battery powered meters because of the power
397 usage related with the technologies that should fulfil these requirements. Where possible
398 alternative approaches should be explored to mitigate privacy risks where requirements
399 cannot be accommodated.
400

401 Furthermore it is important to note that a list of generic P&S requirements can only serve as
402 a guideline for reference purposes by TCs and member states.
403

404 3 **REPOSITORY OF SECURITY REQUIREMENTS**

405

406 3.1 **Introduction**

407

408 The SM-CG Privacy & Security Task Force aims to reach a multi-stakeholder, European
409 wide approach for identifying (technological and economic) security and privacy risks for
410 smart metering in order to be able to derive appropriate requirements and countermeasures
411 based on smart meter use cases. This contributes to ensuring interoperability on European
412 level for products and systems in smart metering. It also facilitates greater economies of
413 scale and supports different market models.

414

415 As a part of the European approach, the Task Force created a repository of privacy &
416 security requirements related to smart metering. In the current stage of the work, the
417 repository is kept in an Excel file. This section provides background to this repository.

418

419 3.2 **Scope**

420

421 The collected privacy & security requirements can be divided into requirements related to the
422 business (governance, processes, organization) and requirements related to the advanced
423 metering infrastructure (functionalities, information, communication and physical
424 requirements).

425

426 3.3 **Sources**

427

428 The repository has been built by collecting privacy & security requirements from the following
429 sources:

- 430 - Dutch Privacy and Security requirements of the AMI (version 2.0)
- 431 - U.K. Industry's Draft Technical Specifications
- 432 - SM-CG requirements repository
- 433 - ENISA - Appropriate security measures for smart grids
- 434 - NIST-7628 (U.S.A.)
- 435 - ISO27001:2005 – Annex A – controls & objectives
- 436 - Comments from stakeholders

437

438 The following section describes which method has been used to select the privacy & security
439 requirements from the sources mentioned above.

440

441

442 3.3.1 Dutch Privacy and Security requirements of the AMI (version 2.0)

443

444 Whereas the Dutch Smart Metering Requirements (DSMR 4.0) contain general AMI
445 requirements and requirements derived from NTA 8130 (the Dutch architecture definition),
446 the AMI P&S requirements (version 2.0) formulated by Netbeheer Nederland have a slightly
447 different scope:

- 448 - The organisational aspects of setting up and managing the AMI within grid operators'
449 organisations are included in the scope.
- 450 - All systems and devices within the advanced metering infrastructure, from the meter
451 up to and including the interface between the grid operators and other market parties
452 (P4), are included in the scope.
- 453 - The information types to which these requirements apply are explicitly defined (e.g.
454 connect/disconnect is included in scope).
- 455 - The processes to which these requirements apply are explicitly defined (e.g.
456 installation, asset management ...).
- 457 - The following elements are deemed out of scope:
 - 458 o Smart grids – local devices that control these grids;
 - 459 o Advanced grid management using information about domestic consumption;
 - 460 o Next generations of PLC communication;
 - 461 o Next generations of data communication;
 - 462 o 'Meshed-RF'.

463

464 The security requirements in version 2.0 have been based on a risk analysis which in its turn
465 was based on a list of high level security goals. These security goals have been defined
466 based on a "rule base" (e.g. security standards, European / national legislation) which was
467 compiled after performing a stakeholder analysis. Additionally, the requirements are linked
468 with identified threats in version 2.

469

470 3.3.2 U.K. Industry's Draft Technical Specifications

471

472 This document contains an overview of the UK communication architecture and a large
473 number of extended functional requirements, none of which touch on security. There is
474 however a separate chapter listing the security requirements. These were based on a risk
475 assessment.

476

477 **Important note:** The requirements presented in this document are only those that have a
478 functional or technical impact on the design and implementation of a customer premises
479 Smart Metering system. They are not intended to mitigate every risk in the end-to-end
480 system and require the support of the wider requirements set (e.g. many security risks are
481 partially addressed by monitoring controls within the DCC and/or its Users).

482

483 3.3.3 **SM-CG requirements repository**

484

485 The security requirements of the Smart Meters Coordination Group, Task Force use cases,
486 were developed based on the SM-CG architecture and use cases and were all taken into this
487 repository (see reference [4]).

488

489 3.3.4 **ENISA – Appropriate security measures for smart grids**

490

491 This document provides technical guidance addressing security of smart grid networks and
492 services which are critical and whose malfunctioning would have a significant impact on
493 society. Data privacy issues, however, are considered out of scope of the document.

494 Since this document was developed based on similar sources as in our requirement
495 repository, there was already quite a lot of overlap. Where gaps were identified, requirements
496 from this guidance document were taken over in the repository.

497

498 3.3.5 **NIST-7628 (U.S.A.)**

499

500 Within the smart grid, NIST defines 130 logical interfaces, grouped in 22 interface categories
501 which belong to one of 7 smart grid domains. While some security requirements apply in all
502 cases, some security requirements' applicability depends on the interface category and/or
503 the security level.

504

505 The scope of ESMIG's smart metering security approach was mapped to logical interface
506 "U24", which belongs to interface category 18. Security requirements that are not applicable
507 to interface category 18, are marked with "out of scope"; these could in principle be removed
508 from the repository because they are not in scope, but have been left in for reference. The
509 NIST maps the security requirements to three security levels; this mapping is also taken over
510 in this repository.

511

512 3.3.6 ISO27001:2005 – Annex A – Controls & objectives

513

514 This document provides organizational requirements for information security. This standard
515 is not specific to smart metering / grids but is very good to complement the repository where
516 some gaps were still present. It is also clear that the smart metering specific requirements
517 (see 3.3.1 - 3.3.5) have also taken ISO27001 into account since there is quite some overlap
518 with this standard.

519 Note that currently the 2005 baseline of the standard is referred to; in September 2013 this
520 information security standard has been replaced by a newer version ISO/IEC27001:2013.

521

522

523 3.4 Requirements uniformity

524

525 The requirements of different countries are defined based on a country-specific smart
526 metering architecture. In order to make a consistent repository out of these requirements, the
527 national architecture elements were replaced by the architecture elements of the SM-CG
528 functional architecture as detailed below.

529

National architecture element	SM-CG architecture
UK - Communication hub	LNAP
UK - Core devices	Smart meter & display
UK - HAN	LNAP
UK - Handheld Device	Handheld device
UK - Smart metering system	AMI
UK - Core devices & systems	AMI
UK - end-to-end system	AMI
NL - Data concentrator	NNAP
NL - Smart metering system	AMI + LNAP
NL - P1	(Port on) Smart meter H1
NL - P2	(Port on) Smart meter M
NL - P3	(Port on) Smart meter G
NL - P4	Interface from Meter Data Collector to other market parties
NL - Central system	HES
NL - Equipment	AMI
NL - Grid operator	Market role operating the AMI

530

Figure 4 – Architecture element mapping

SM-CG Sec073_DC

531

532 Furthermore, as can be expected, there was overlap between the different sets of security
533 requirements. This overlap has been identified and removed.

534

535 3.5 **Overview of the requirements repository**

536

537 See Annex A

538

539 4 **PRIVACY**

540

541 4.1 **Results of DPIA application to SM-CG Use Cases**

542

543 The Task Force has organised and participated in workshops where the Data Protection
544 Impact Assessment (DPIA) developed by EG2 (see section 2.2.4) has been applied to one or
545 more Use Cases developed by the Task Force “Use Cases” of the SM-CG (see reference
546 [3]). This section gives a summary of the results of these workshops. The information can be
547 used as input when performing a DPIA on Smart Metering Use Cases in local/national
548 situations.

549

550 As indicated in section 2.2.4, in the first step, six criteria are checked to determine the need
551 for conducting a DPIA. One of the criteria is to check if personal data is involved. Regarding
552 Smart Metering it is important to have a clear definition of the data captured by the meter and
553 for what purpose. The definition of when data is to be considered to be personal should be
554 further explained. Basically it concerns all data that can be linked to an individual, even if this
555 link is made outside the scope of operation of the concerning operator (e.g. meter <->
556 consumer). Data that cannot be influenced by this individual (e.g. technical characteristics of
557 the meter) is not considered to be personal however.

558

559 A data processor also has its responsibilities regarding data protection, even if this
560 organisation only transfers encrypted data. The risk of accessing or manipulation encrypted
561 data only is lower, so the need to protect data is limited. It is the responsibility of a data
562 controller to perform the DPIA, taking into account the responsibilities of the relevant data
563 processors. Typical examples are the DCC as data processor and the retailer as data
564 controller in GB.

565

566 In the first steps of the DPIA, the analysis does not have to be in depth since the objective is
567 only to determine if a DPIA has to be performed. Later on separate risk analyses will prompt
568 consideration of what concrete information security and privacy requirements are needed,
569 taking account of the specific risk to the individual, the nature of the system/application etc.

570

571 In the third step of the DPIA, the relevant system and information assets are identified.

572

SM-CG Sec073_DC

573 In the case of Smart Metering the SM-CG functional reference architecture identifies the
574 systems and data interfaces.

575

576 Note: The use of the term “Actor” in the SM-CG Use Cases is not exactly similar to the way it
577 is used in the DPIA. While the SM-CG Use Cases make a difference between external and
578 internal actors, EG2 only refers to external actors (for SM-CG the users of the reference
579 architecture) and identifies internal actors (in SM-CG Use Cases: system components) as
580 “Supporting assets”.

581

582 In case of remote meter reading (Use Cases “Obtain meter read on-demand” and “Obtain
583 scheduled meter reading” , see reference [3]), the primary assets are meter data elements
584 such as:

585 **Billing data:** All data measured by the meter - consumption and demand per tariff, load
586 profiles - that is necessary to establish the bill;

587 **Local generation data and management:** Measurement and management data related to
588 energy generated locally;

589 **Supply and load control:** status of the switches;

590 **Contractual data:** Data generated by the meter related to the contract and contract
591 changes, including price information, payment tokens. This is particularly relevant for smart
592 meters operating in payment mode;

593 **Power quality data:** Data measured by the meter related to power quality, like voltage
594 surges, voltage dips, power outages, harmonics;

595 **Tamper data:** Data related to tamper events - physical, electromagnetic, metrology,
596 communication related - detected by the meter;

597 **Technical data (meter health):** Data related to the operation of the meter, in particular total
598 operating time and per tariff, battery voltage, battery life, number of operations of the supply
599 and load control switches, internal temperatures etc.;

600 **Communication related data:** Number of connections, statistics on good and erroneous
601 messages.

602

603 In the following steps of the DPIA, identification of the relevant risks and a risks analysis can
604 be performed, based on the Smart Metering

605 - System architecture (see also SM-CG reference architecture, reference [1])

606 - System components (internal actors / supporting assets)

607 - System Users (actors)

SM-CG Sec073_DC

- Use Cases (see also SM-CG repository of Use Cases, reference [3])
- Primary assets (see list of data elements above)

Finally when privacy controls are identified (DPIA step 6), these can be linked to the relevant Use Case steps in the column for Technical Requirements. The figure below shows an example where various technical requirements, among which are privacy requirements/controls, are linked with Use Case steps.

Scenario Name :		Basic Flow				
Step No.	Event	Description of Process/Activity	Information Producer	Information Receiver	Information Exchanged	Technical Requirements ID
1	Actor A decides he wants a particular meter read or meter reads.	The request is sent to the HES.	Actor A	HES	Meter Data Request	
2	HES receives the request	The HES checks Actor A's access rights and triggers a meter read through a pull communication, invoking secondary UC SU3.				TR-Conf 6/7/8/9 TR-QoS n 1 TR-SEC 21 TR-PRIV 3
3	The HES receives the requested data	The HES creates and sends a response message.	HES	Actor A	Metering Data	

Figure 5 – Link between technical requirements and Use Case steps

The figure below shows examples of technical requirements / controls related to privacy that were gathered by the Task Force Use Cases (see reference [4]).

Req. TR-PRIV	Owner	Relevant to use case	Specification
1	TC294	ALL	Data integrity is preserved in all data exchanges.
2	TC294	ALL	Confidentiality of critical data is preserved in all data exchanges
3	TF use cases	BI.01	The actor requesting the meter read information has the right / is authorized to obtain this specific information.
4	TF use cases	BI.02	The frequency of the transmission of the reading does not exceed requirements for billing unless the consumer has given explicit permission.
5	ETSI	ALL	The ETSI M2M gateway (on each interface of the LNAP / NNAP / HES) checks that requested data respects the privacy policy.

624

5 STATUS OF THE WORK BY TECHNICAL COMMITTEES

625
626

5.1 TC13

627
628

The TC13 WG02 Privacy and Security taskforce has been carrying on the work of bringing security extensions to the IEC 62056-x DLMS/COSEM standard, in order to address national security requirements of member states. A new version of the IEC 62056-5-3, 62056-6-1, 62056-6-2 DLMS/COSEM standards has been published this year and provides application layer level cryptographic protection of messages exchanged between DLMS/COSEM clients and servers. The crypto-algorithm chosen is AES-GCM 128 as defined in the NIST SP 800-38D publication and provides authenticated encryption. For the transport of new security keys, the NIST AES key wrap algorithm has been specified.

637

The DLMS User Association security task force is working to extend the security model with asymmetric cryptography to support end-to-end protection of messages between one or multiple third parties and smart meters via DLMS clients acting as brokers. The new algorithms comply with the NSA Suite B, i.e. elliptic curve digital signature (ECDSA) and elliptic key Diffie-Hellmann key agreement (ECDH) using P-256 and P-384 NIST named curves. Multiple protection layers can be composed and applied by different parties along the communication chain. These protection algorithms can be applied the same way on privacy sensitive data conveyed in COSEM objects. The security level is configurable in relation with the security use cases of the project via security policies and access rights applied to COSEM object attributes and methods both on requests and responses, limiting overhead and providing flexibility.

641
642
643
644
645
646
647
648

649

650 This on-going work should be completed by the DLMS UA by end of 2013, and then the
651 results will be brought to the IEC.

652

653 5.2 TC205

654

655 In its plenary in November 2013, TC205 has again endorsed its conclusions laid down in the
656 AHWG PS report V1 (SM-CG Sec0064_DC):

657

658 *“Security is ensured by the Smart Meter (for H1-interface) and the LNAP / NNAP (for the H2-
659 H3 interfaces), all connection points between home/building and WAN are secured.*

660 *Therefore, there is no need for additional security precautions for the SG Demand Side
661 elements that are in scope of TC205 WG16 &18.*

662 *Therefore, there is no need for additional security precautions for the SG Demand Side
663 “behind” the gateway”*

664

665 As priority is set on the development of the Data Modelling standards (prEN50491-11 and
666 prEN50491-12), there will be no additional work on the topic until mid-2014.

667 However, in a second phase, TC205 WG16 and WG18 look forward to apply the SGIS tool
668 box in order to refine the PS requirements for HBES.

669

670

671 5.3 TC294

672

673 This section summarizes the current status of work in CEN/TC 294 succeeding the process
674 referenced in the previous report “Smart Meters Coordination Group Privacy and Security
675 approach – part I (April 2013)” (reference [2]).

676

677 In 2012 CEN/TC 294/WG 4 started the work on security amendment. An intensive discussion
678 within the working group showed a conflict between security demands of the smart meter
679 system, which should resist attacks during the long life time of meters and the hard limitation
680 of energy and computation power of a battery operated meter. Therefore no consensus was
681 found, the issue of unsolved security amendment was sent back to the CEN/TC 294 end of
682 2012.

683

684 The following is an extract of the decision for action during last CEN/TC 294 plenary:

685

686 **DECISION 143/2012 – Assignment on data security requirements (privacy, integrity**
687 **and authenticity) regarding CEN/TC 294 standards**

688

689 **CEN/TC 294 ...**

690 – decides to **allocate the following tasks to the working group CEN/TC 294/WG 4**
691 with respect to security (privacy, integrity and authenticity):

692 (a) analyse and identify the constraints (technical and economic) for security handling in
693 the metering world within the scope of CEN/TC 294;

694 (b) elaborate an overview of current levels of security technology for communication;

695 (c) analyse solutions for key distribution (single/multiple) and key exchange (secret/public
696 and private)

697 – requests that the outcome of the above assignment shall be documented by
698 CEN/TC 294/WG 4 and reported to CEN/TC 294.

699

700 The working process started immediately by expert meetings and web-sessions, tasking
701 subgroups with dedicated items and involving external experts from other domains.

702

703 The report tries to value the needs of secure system architecture against the additional effort
704 and cost for the commissioning and operation of such a system.

705

706 Major results of the report from analysis and discussion topics:

707 ▪ Description of constraints in CEN smart metering (technical and economic)

708 ▪ Identification of State-of-the-art security mechanisms with a subset applicable for
709 Smart Metering

710 ▪ Overview of potential market roles in future smart metering systems and relationship
711 to measured or process data of meters

712 ▪ Threats and risks analysis with impact, likelihood and security measures

713 ▪ Supporting two modes of security architecture - an End to End security (Transparent
714 mode) as well as a separation of security elements for data provided from meter
715 device and data accessed by the operator or consumer (Data processing mode)

716 ▪ Description of cryptographic algorithms and key management

717

718 This report focuses on security elements needed for secure communication between meter
719 and communication partner (gateway).

720

721 **Conclusion**

722 Based on a risk analysis the report of WG4 recommends the security services Privacy, Data
723 Integrity, Authentication for a smart meter. The Security level should be augmented by
724 services like Key derivation or Key distribution. All security services bases on symmetrical
725 cipher methods like AES128, to consider the power limitation of battery operated devices.

726

727 It is noted that a standard for meter communication supporting these security services allows
728 the establishment of a secure smart meter system. However the standard itself is not able to
729 ensure a secure smart meter system.

730

731 The report was presented to CEN/TC 294 in the Plenary 13th of November 2013. The TC294
732 Plenary accepts this report and decides to start a preliminary work item for the realization of
733 the Security amendment of the EN13757-3. This will be handled by the WG4.

734

735

736 5.4 **ETSI**

737

738

739 5.4.1 **Work on security**

740 ETSI TC M2M has developed a general approach about security in close relationship with
741 the M2M architecture, as to be able to include in the architecture itself the security
742 requirements in an End to End Vision. WG2 (architecture) and WG4 (security) have
743 developed specifications that include the link from the “device” to the “service platform” into
744 the network, when this link is

745

746 The deliverables specifically related to smart Metering and security in ETSI SmartM2M are:

747

748 - ETSI TR 103.118 Machine-to-Machine communications (M2M); Smart Energy Infrastructures
749 security; Review of existing security measures and convergence investigations
750 [Extension and harmonization of Smart Energy Security Solutions](#)

751 - Review of security methods provided by deployed standards used in the Smart Energy
752 industry (e.g. IEC 62351, IEC 62443...) or mandated by regulation (e.g. Requirements from
753 the German BSI for Smart Meter Gateways and Secure Element) as well as gaps identified by

754 the Smart Grid Information Security group for the M/490 mandate, in order to identify areas
755 where ETSI in general and ETSI TC M2M in particular may bring additional value, e.g. by
756 extending or harmonizing security solutions where possible. This could result in
757 recommendations for areas of work shared with other ETSI groups (for potential actions falling
758 outside the scope of TC M2M), new work item(s) proposals, or CRs within the scope of ETSI
759 TC M2M, as applicable.

760
761 A Stable draft is expected on S1 2014, that will be communicated to SMCG and SGCG.
762

763 5.4.2 **Work on Privacy**

764 Note : ETSI TC M2M did not conduct formalized study work on Privacy for the moment, even
765 if requirements and questions have already come, at a general level. Some discussions have
766 been initiated concerning the data coming from geolocalized devices and containing an
767 identifier which is a human owner for example. Their full availability on the Web set up trivial
768 Privacy concerns.
769

770 In the work Item : DTR/SmartM2M-00021, with document TR 103.118 under construction, a
771 paragraph related to Privacy for Smart Metering and Smart grid Communication and Information
772 System chain will be included, in collaboration with utilities and with energy equipment manufacturers,
773 working in their Technical committees (CLC TC13, CLC TC 205, CEN TC294).
774

775 5.4.3 **EC Workshops and Expert group Works.**

776
777 An expert group mandated by the EC DG CNECT for evaluating the needs for setting in
778 place the Internet of Things, has made a study to evaluate how the individual end user can
779 slow down the process when he does not trust the system or if he experiences privacy
780 concerns.
781

782 All the public information on the Internet of things can be found on the Digital Europe website
783 at <http://ec.europa.eu/digital-agenda/en/news/conclusions-internet-things-public-consultation>

784 The public consultation was held between April and July 2012 (see [IP/12/360](#)). 600 people,
785 associations and various groups from academics and civil society, as well industry players responded
786 to the consultation. Through the public consultation, the Commission sought views on an a policy
787 approach to foster a dynamic development of Internet of Things in the digital single market while
788 ensuring appropriate protection and trust of EU citizens.
789

790 The chapter 7 related to Security and Privacy can be consulted at the address :
791 http://ec.europa.eu/information_society/newsroom/cf/dae/document.cfm?doc_id=1753
792

793 The document addresses propositions of European policy, with needs of standards for
794 Security, and Code of Conduct book for Privacy.
795
796

SM-CG Sec073_DC

797 Note : TC M2M delegates and security experts working in various ETSI TCs including TC
798 M2M, participate actively to tasks related to security including M441, M490 and M462,
799 and are often individually requested to provide expertise into their National Body
800 (example : DIN, AFNOR, AENOR, etc). Moreover they also participate to Workshops and
801 Studies organized by the European Commission.
802 (examples tbd)
803
804

805 6 **COMPARISON OF SECURITY CERTIFICATION SCHEMES**

806

807 6.1 **Comparison CC – CPA – CSPN – ISO/IEC 19790 & 24759**

808

809 6.1.1 **Introduction**

810

811 **Acronyms**

812

CC	Common Criteria
CPA	Commercial Product Assurance
CSPN	Certification de Sécurité de Premier Niveau
CEM	Common Criteria Evaluation Methodology
PP	Protection Profile
EAL	Evaluation Assurance Level
OAM Actor	Operation / Administration / Maintenance Actor
SPD	Security Problem Definition
CB	Certification Body
ANSII	Agence Nationale de la Sécurité des Systèmes d'Information
CCMC	Common Criteria Maintenance Committee

813 **Scope and objectives**

814

815 The objective of this chapter is to describe security certification schemes³ related to
816 information security, looking at requirements they define for developers of a product and on
817 relevant inherent features of the schemes. The document attempts to summarize the most
818 relevant differences between the security certification schemes in scope, without implying
819 that one scheme would be better than another. It is up to regulators and the market to decide
820 which certification scheme enforces the required level of trust in a given situation.

821

822 One key aspect in this document is to distinguish the technical aspects of the testing or
823 evaluation standard which a specific security certification scheme may be using from the
824 legal foundation and international recognition of the scheme itself.

825

826

827

³ Currently there are no certification schemes in the privacy area.

828

829 The schemes in scope are:

- 830 - *Common Criteria* (CC), which is an international scheme
- 831 - *Commercial Product Assurance* (CPA), which is a scheme from Great Britain
- 832 - *Certification de Sécurité de Premier Niveau* (CSPN), which is a French certification
- 833 scheme.

834

835 6.1.2 Overview of certification schemes

836

837 The following section briefly explains the scope, organization and evaluation methodology of
838 the certification schemes in scope.

839

840 6.1.2.1 Common Criteria (CC)

841

842 Scope

843 Common Criteria are an industry-independent / product independent scheme. At present,
844 certified products belong to a wide array of categories going from access control systems to
845 operating systems and biometric systems and devices. Common Criteria offer pre-defined
846 evaluation assurance levels (EAL), corresponding to increasing assurance efforts and
847 vulnerability testing. A certification roughly consists of two different activities:

- 848 • Defining and assessing a consistent set of security requirements against a given
849 security problem
- 850 • Assessing that a product is compliant with these security requirements.

851

852 These two activities are defined in ISO/IEC 15408 (also called *Common Criteria for*
853 *Information Technology Security Evaluation*) and the associated Common Criteria Evaluation
854 Methodology (CEM).

855

856 The Common Criteria allow the creation of a **Protection Profile** (PP) which is a set of
857 security requirements for a type of product which may support many different
858 implementations. The security requirements are derived from a set of security objectives that
859 cover the security problem definition consisting of threats, assumptions and policies.

860

861 Organization

SM-CG Sec073_DC

862 The scheme is maintained under and international arrangement and endorsed by a group of
863 national authorities (**Certification Bodies**). A Certification body (called CB hereafter) is
864 generally a governmental agency or bureau of the national defence ministry.

865

866 Any Common Criteria evaluation relies on competent and independent licensed laboratories.
867 These **Evaluators** (also called *laboratories* or *ITSEF: Information Security Evaluation*
868 *Facility*) are accredited by a national standardization entity, and licensed or otherwise
869 approved by the national Certification Body.

870

871 Evaluation methodology

872 The Common Criteria consists of the following catalogues:

- 873 - CC-Part 1: presents the conceptual framework of the methodology and is intended to
874 developers as well as evaluators.
- 875 - CC-Part 2: describes a comprehensive series of standardized security (functional)
876 requirements
- 877 - CC-Part 3: lists a comprehensive series of standardized security assurance
878 requirements, which describe how a product should be evaluated.
- 879 - CEM: which defines the minimum actions to be performed by an evaluator in order to
880 conduct a CC evaluation

881

882 6.1.2.2 **Commercial Product Assurance (CPA)**

883

884 Scope

885 CPA⁴ (Commercial Product Assurance) is a national GB scheme intended for commercial
886 security products. CPA is defined and maintained by CESG (Communications Electronic
887 Security Group – the Certification Body), which directly accredits evaluation laboratories
888 (CPA Test Labs). The scheme aims at demonstrating compliance to national requirements,
889 while rationalising legacy national schemes and maintaining the value of previously issued
890 certificates.

891

892 CPA covers only specified types of products/features of products, while Common Criteria is
893 industry / product independent. Examples of products covered by CPA are data sanitation,

⁴ CPA is a recent scheme and is still under modification. Some of the information in this report may change in the future.

SM-CG Sec073_DC

894 VPN's, firewalls ... Other types of products are in progress, such as smartphones or
895 hardware security modules.

896

897 CPA offers one assurance level: Foundation Grade. This grade is intended for COTS
898 (Commercial Of-The-Shelf) products used to process information classified as *official* in the
899 new Government Classification Policy.

900 The two other tiers of this classification policy (secret and top-secret) require bespoke
901 equipment to be evaluated under the CAPS (CESG Assisted Products Service) scheme.
902 CAPS evaluation is performed by CESG itself, instead of commercial laboratories such as in
903 CPA.

904

905 Organization

906 As mentioned above, CESG is GB Certification Body. It accredits evaluation laboratories and
907 maintains CPA.

908 Evaluation laboratories are called CPA Test Labs. Such laboratories perform evaluation of
909 products for foundation grade certifications only. Evaluation laboratories mainly use evidence
910 created by the developer, but can be led to create specific tests in order to check
911 requirements left untested by the developer. Furthermore, cryptographic evaluation cannot
912 be performed by the developer; it must be performed by an independent entity, if not by the
913 evaluation laboratory.

914

915 Evaluation methodology

916 The evaluation methodology relies mainly on Security Characteristics (SCs) and the CPA
917 Build standard.

918

919 **The Security Characteristics** define the expected security features of the product; they are
920 focused on functions and are product specific (e.g. specific for data sanitation, VPN's,
921 firewalls, etc.). Security Characteristics play a similar role to the Protection Profiles in CC.

922 In the beginning of an evaluation, the evaluation laboratory refines the applicable Security
923 Characteristics into Tailored Security Characteristics. Tailored Security Characteristics play a
924 similar role as Security Targets in CC.

925

926 **The CPA Build Standard** defines the assurance requirements for product development and
927 breaks into twelve high-level requirements addressing four themes:

- 928 • Configuration Management

- 929
- Flaw remediation
- 930
- Testing
- 931
- Developer security measures

932

933 Such requirements are somewhat similar to CC components listed in CC-Part3.

934

935

936 6.1.2.3 **Certification de Sécurité de Premier Niveau (CSPN)**

937

938 Scope

939 The CSPN is a French scheme defined by ANSSI that aims at providing a first-level security
940 certification for IT security products. Its scope is similar to Common Criteria, with the
941 following specificities:

- 942
- The assurance process is simplified
- 943
- The evaluation is focused on compliance and vulnerability analysis
- 944
- The actors are committed to a given evaluation duration and cost

945

946 IT products can currently apply to CSPN if they belong to a specific list of domains (e.g. data
947 deletion, firewalls, secure communication, etc.). This list is regularly updated to address new
948 needs.

949 It should be noted that standard CSPN excludes products too complex to be evaluated in an
950 expected duration and cost and products including non-standard cryptography.

951

952 Organization and evaluation methodology

953

954 The process is similar to the Common Criteria process. Instead of applying CC security and
955 assurance requirements (see CC part 2&3) the developer uses guidelines described in
956 CSPN. CSPN also has common features with CPA, especially the domain-specific approach.

957

958

959 6.1.2.4 **ISO/IEC 19790:2012 and ISO/IEC 24759:2013**

960

961 Scope

962 These two standards are the ISO counterpart of the US NIST FIPS 140-2, Security
963 requirements for cryptographic modules and the derived test requirements. As such, ISO/IEC

SM-CG Sec073_DC

964 19790 and ISO/IEC 24759 are applicable to validate whether the cryptographic core of any
965 security product is properly implementing an approved suite of cryptographic protocols,
966 modes of operation and key sizes, while protecting this implementation and the critical
967 security parameters, like keys, in accordance to the design and specification requirements
968 laid out in the standards. There are four levels of security defined, and ISO/IEC 19790
969 contemplates a variety of possible implementations, both software and hardware.

970

971

972 Organization

973 Compliance to ISO/IEC 19790 is an open matter, in accordance with the existing European
974 regulations dealing with product compliance. Since this or an equivalent harmonised
975 standards not referred in any European Directive, it is not subject to the usual requirements
976 for Certification Bodies to operate under Notified Bodies, but Certification Bodies for ISO/IEC
977 19790 are simply subject to accreditation under the applicable national accreditation entity.

978 The European co-operation for Accreditation (EA), and more specifically, the EA Multilateral
979 Agreement (EA MLA) ensure cross-European recognition of ISO/IEC 19790 product
980 compliance certificates.

981

982 Evaluation methodology

983 ISO/IEC 19790 and ISO/IEC 24759 are conformity testing standards, so products are tested
984 for compliance against the applicable and very specific requirements, leaving out much of the
985 subjectivity required for security evaluation. The requirements are set in ISO/IEC 19790, and
986 the derived tests are specified in ISO/IEC 24759.

987 The conformity testing of the cryptographic protocols demand the existence of a reference
988 implementation, and a standardized protocol to verify the correctness of the algorithm
989 implementation, that allows a quick verification process. The requirements that apply to the
990 cryptographic module need to be re-instantiated by the tester for each product.

991 The whole process is usually faster and cheaper than an equivalent security evaluation.

992

993 6.1.3 **Roles in certification**

994

995 The following play a role in the certification process:

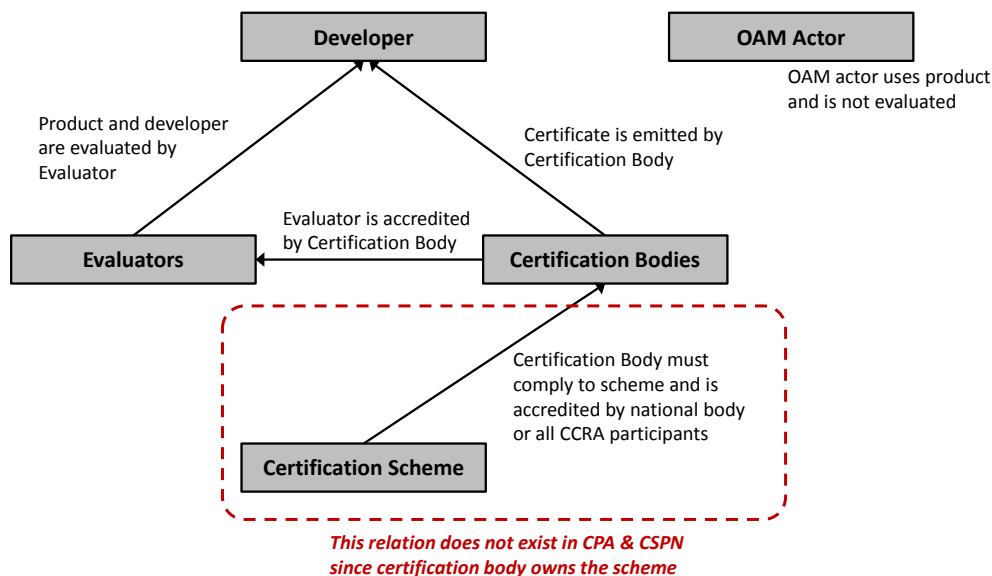

- 996 - The **developer** of the evaluated product must ensure that he himself as well as his
997 product complies to a set of requirements;

- 998 - The **evaluator** assesses whether the developer and the evaluated product complies
- 999 to a set requirements;
- 1000 - The **certification body** accredits the evaluator and emits the certificate for the
- 1001 evaluated product. In case of CC, it needs to comply to certain requirements;
- 1002 - The **certification scheme** is a separate entity in case of CC (see below).

1004 The **actor in charge of Operation / Administration / Maintenance (OAM)** of the evaluated
 1005 product, is himself not evaluated, but is an important stakeholder since several requirements
 1006 will relate to guiding and supporting him.

1007 The figure below summarizes the role and relation between these actors.

1008

1009

1010

1011

Figure 7 - Roles in certification

1012 The developer, evaluator and OAM-actor play similar roles in CC, CPA and CSPN.

1013

1014 In CPA and CSPN, the certification body is owner of the certification schemes, which implies
 1015 that the certification body does not need to comply with specific requirements. In CC at the
 1016 other hand, the certification scheme is managed by a separate body, the Common Criteria
 1017 Management Committee (CCMC). Since in this case, one certification body does not “own”
 1018 the scheme, it has to follow the requirements of the CC Recognition Agreement (CCRA) and
 1019 be accredited by a national accreditation body (or by all CCRA participants) before being
 1020 able to issue certificates and accredit evaluators.

1021

1022 6.1.4 **High level comparison of schemes**

1023

1024 6.1.4.1 **Introduction**

1025

1026 The very principle of existing security certification schemes consists in guaranteeing
1027 confidence:

- 1028 - In a set of certified products or services;
- 1029 - Between several actors of a given domain or activity (particularly the providers of
1030 products and services).

1031

1032 In the smart metering domain, some actors have a “**need for trust**” regarding the products
1033 or services they will use (e.g. the consumer, the regulatory actors, the utility, etc...). Some
1034 actors symmetrically have a “**need to be trusted**”, such as developers and actors operating,
1035 administrating and maintaining the system (OAM actors).

1036

1037 The criteria used to compare certification schemes will be deduced from the trust
1038 relationships they have to enforce.

1039

1040 A certification scheme typically enforces:

- 1041 1. **Trust in the products or services;**
- 1042 2. **Trust in developers and OAM actors.** Trust in these actors is obtained through
1043 assurance by evaluators and certification bodies. This assurance is valid only to the
1044 extent that the certification **scheme can be trusted.**

1045 Following the above, the two key questions that a certification scheme typically addresses
1046 are:

- 1047 1. **How to enforce trust in products or services?**
- 1048 2. **How to enforce trust in the certification scheme itself?**

1049 In the following tables, we will compare 4 certification schemes (CC – CPA – CSPN –
1050 ISO/IEC 19790 & 24759) on how they address these questions.

1051

1052 6.1.4.2 **Enforcing trust in products**

1053

1054 The following are elements that contribute towards the developer enforcing trust in his
1055 products:

- 1056 1. Implement security requirements which cover a threat analysis;

SM-CG Sec073_DC

- 1057 2. Test their products;
1058 3. Define security measures to prevent unauthorized access or modification of products
1059 / services within their premises;
1060 4. Use proven methods and maintain skills within their teams;
1061 5. Provide the end-user with security-related information and obligations and commit on
1062 flaw remediation delays.

1063

1064 In the following table, these points are described more in detail. Furthermore, for each
1065 criterion, we indicate whether or not it is fully or partially covered by each of the certification
1066 schemes. Note that Annex B contains more information on the elements below. Also note
1067 that as stated above, the extent to which criteria are covered by the schemes in scope does
1068 not imply that one scheme would be better than another. It is up to regulators and the market
1069 to decide which certification scheme enforces the required level of trust in a given situation.

SM-CG Sec073_DC

Criteria	Description / sub criteria	CC	CSPN	CPA	ISO/IEC19790
Security requirements based on threat analysis	The certification scheme demands that security requirements are defined as countermeasures to specific threats .	Fully covered	Fully covered	Fully covered	Not covered
Product testing	The certification scheme requires that functional testing takes place by and/or is reviewed by an evaluator. <i>During functional testing, the functions of a product are tested; this includes security function testing, test of the user guidance, testing of protection against misuse, regression testing (re-testing after product changes), etc.</i>	Fully covered (depth depends on EAL)	Fully covered	Fully covered	Fully covered
	The certification scheme requires evaluators to perform vulnerability testing . <i>Examples of such tests are penetration testing, reviewing the security architecture, testing vulnerabilities based on source code, etc.</i> Within this context “partially covered” means that only basic vulnerability testing is performed without for example penetration testing.	Fully covered (depth depends on EAL)	Partially covered	Partially covered	Not covered
Defining security measures for the premises of developers / OAM actors	The certification scheme demands that developers take measures to secure their premises (e.g. through access control, human resource security ...)	Fully covered (depth depends on EAL)	Optional	Fully covered	Not covered
	The certification scheme required that user guidance is provided to secure the product during operation/administration/maintenance.	Fully covered	Fully covered	Fully covered	Fully covered
Use of proven methods and maintaining skills	The certification scheme demands that configuration management requirements are put in place. This ensures consistency of a product's	Fully covered	Optional	Fully covered	Fully Covered

SM-CG Sec073_DC

<p>performance, functional and physical attributes with its requirements. <i>An example of such a requirement is "All constituent components that are used to create the finished product must be uniquely identified."</i></p>	(depth depends on EAL)			
<p>The certification scheme requires that third-party tools and components are properly managed. <i>For example through procedures for acquisition, reception and testing, installation, patching, etc. of third-party tools.</i></p>	Fully covered (depth depends on EAL)	Not covered	Fully covered	Not covered
<p>The certification scheme requires that developers are properly trained on security related subjects.</p>	Optional	Optional	Fully covered	Not covered
<p>The certification scheme demands that sufficient user guidance is being provided to actors responsible for operation / administration / maintenance of the system.</p>	Fully covered	Fully covered	Fully covered	Fully covered
<p>The certification scheme requires a flaw remediation procedure tracking (amongst others) product flaws, their effects, corrective measures, etc.</p>	Fully covered (depth depends on EAL)	Not covered	Fully covered	Not covered
<p>The certification scheme requires a documented lifecycle model (formalization of product specification design documentation, requirements traceability, etc.) providing for the necessary quality control over the development and maintenance of the product.</p>	Fully covered (depth depends)	Not covered	Not covered	Fully covered (depth depends on security level)

SM-CG Sec073_DC

		on EAL)			
Committing to flaw remediation obligations, delays and information provision to end-users	The certification scheme requires a procedure for providing information to end-users on identified flaws and security incidents. Furthermore, it requires that timely action is taken for flaw remediation.	Fully covered (depth depends on EAL)	Not covered	Fully covered	Not covered

Table 1 - Enforcing trust in products

1070

1071 6.1.4.3 **Enforcing trust in the certification scheme itself**

1072

1073 As noted above, trust in developers and their products is obtained through assurance by
1074 evaluators and certification bodies. This assurance is valid only to the extent that the
1075 certification scheme itself can be trusted. In order to achieve this, the scheme can:

- 1076 1. Strive for (national / international) recognition
1077 2. Define strong criteria for accreditation of the Certification Body
1078 3. Provide sufficient information to stakeholders
1079 4. Guarantee the technical relevance of the methodology
1080 5. Guarantee the business relevance of the methodology

1081

1082 In the following table, these points are described more in detail. Furthermore, for each
1083 criterion, we indicate whether or not it is fully or partially covered by each of the certification
1084 schemes. Note that Annex B contains more information on the elements below. Also note
1085 that as stated above, the extent to which criteria are covered by the schemes in scope does
1086 not imply that one scheme would be better than another. It is up to regulators and the market
1087 to decide which certification scheme enforces the required level of trust in a given situation.

1088

1089

Criteria	Description / sub criteria	CC (under the CC Recognition Agreement)	CSPN	CPA	ISO/IEC 19790 and 24759 (under the EA multilateral agreement)
Recognition	Scope of the recognition agreement	Inter-national (17 authorizing members and 9 consuming members)	National	National	Full Europe (35 full members and 13 associate members)
Definition of CB accreditation criteria	The recognition agreement organization defines requirements for accreditation of individual Certification Bodies.	Fully covered	N/A	N/A	Fully covered
	The recognition agreement organization defines criteria for periodic assessment of Certification Bodies' continued compliance to accreditation requirements.	Fully covered	N/A	N/A	Not covered
Information provision to stakeholders	The recognition agreement organization publishes certificates and provides information on accredited certification bodies.	Fully covered	N/A	N/A	Partially covered (only accredited labs)
Technical	The certification bodies facilitate coordination with	Fully covered	Optional	Fully	Fully covered

SM-CG Sec073_DC

relevance of the methodology	technical communities to ensure technical relevance.			covered	
	The methodology covers generic security functionalities like: "Security audit, logs, events & alarms", "Role based access and account management", "Cryptography and key management", etc.	Partially covered	Not covered	Not covered	Fully covered
	The methodology or recognition agreement defines an assurance continuity process after product updates.	Fully covered	Fully covered	Not covered	Not covered
	The methodology supports multiple security/assurance levels.	Fully covered (Evaluation Assurance Levels)	Not covered	Not covered	Fully covered (security levels)
Economics	The scheme includes measures to limit the cost and/or workload and/or duration of evaluation	Not covered	Partially covered (fixed time)	Partially covered (fixed lab fees)	Not covered
Scope	The certification scheme applies to a wider product scope	Fully covered	Partially covered	Partially covered	Not covered (only applies to cryptographic modules)

1090

1091

1092

Table 2 - Enforcing trust in the scheme

1093 **6.2 Certification approaches in European member states**

1094

1095 A survey has been performed by ENISA in cooperation with the Task Force among EU
1096 member states, to gather information on existing certification approaches or concrete plans
1097 to develop such approaches. The outcome of this survey was that Germany, GB and France
1098 are considering the approaches as described in section 6.1.2. Both GB and France have
1099 indicated that they might consider the CC approach in a later stage when this approach can
1100 be adopted according the local requirements. Other countries did not take a decision yet, but
1101 those that are looking at certification schemes, concentrate on CC.

1102

1103 At an ENISA workshop in 2012 the conclusion was drawn that a majority of stakeholders
1104 (from various member states), would prefer a European approach in favor of multiple
1105 different national approaches.

1106

1107 7 **CONCLUSIONS**

1108

1109 Having considered Data Protection Impact Assessment for Smart Metering Use Cases and
1110 collected new Technical Requirements from various sources, the Task Force came to the
1111 following conclusions regarding its further work.

1112

1113 The exercises to apply risk analysis to the SM-CG Use Cases generate valuable information
1114 about the process to define or select the appropriate privacy and security requirements and
1115 controls.

1116

Recommendation 1: Task Force to continue with applying the (newer versions of the) SGIS toolbox and DPIA template to Smart Metering Use Cases in order to improve the process for selection of the appropriate requirements/controls and evaluate the list of requirements made available by the SM-CG.

1117

1118

1119 At the time of writing this report, Expert Group 2 of the Smart Grid Task Force and WP3 of
1120 the SGIS were still working on the DPIA and related lists of privacy threats and controls.
1121 Furthermore EG2 was working on the list of Best Available Techniques to approach privacy
1122 risks. The SM-CG repository of Technical Requirements does not contain the latest list of
1123 privacy related controls and Best Available Techniques created by EG2.

1124

Recommendation 2: Task Force to extend the SM-CG repository of Technical Requirements with the latest Privacy controls and relation to the Best Available Techniques identified by EG2.

1125

1126

1127 When performing a risk analysis it seemed to be important to be able to link the final selected
1128 requirements and controls to identified threats. List with commonly recognized threats related
1129 to Smart Metering and Smart Grids are becoming available through the risk analyses in
1130 some EU Member States and the work of the SGIS group in the SG-CG and EG 2.

1131 Furthermore the study of certification approaches, such as Common Criteria, showed that a
1132 link between security requirements and threats is needed, in order to understand which
1133 threats can be mitigated when complying with specific requirements.

1134

Recommendation 3: Task Force to define a reference list of security threats and link the security related Technical Requirements in the SM-CG repository to the identified threats. Consideration will also be given to privacy threats.

1135

1136

1137 Various stakeholders from EU member states have indicated that they would prefer a
1138 European approach for certification of AMI components on privacy and security aspects.
1139 Some states have adopted approaches based on Common Criteria or similar schemes. CC
1140 is based on the ISO/IEC 15408 standard, but has additional rules to follow in order for
1141 certificates to be accepted in specific EU countries (currently not EU wide). Certificates
1142 based on ISO/IEC standards would be accepted under the general EU rules in all EU
1143 countries.

1144

Recommendation 4: Task Force to investigate if and, if yes, how a European approach should be developed for certification of AMI components on security aspects. Currently there are no certification schemes in the privacy area.

1145

1146

1147 The Smart Grid Coordination Group continues its work in 2014 and the SGIS working group
1148 will further evaluate security standards, privacy recommendations / regulations and develop
1149 the risk analysis toolbox.

1150

Recommendation 5: Task Force to continue its cooperation with the SGIS working group in order to evaluate and improve the applicability of its deliverables for Smart Metering.

1167 9 **ANNEX A: REPOSITORY OF SECURITY REQUIREMENTS**

1168

1169

1170 This is a separate document (spread sheet): reference **SM-CG Sec073_DC**.

1171

1172

1173 10 **ANNEX B: DETAILED DESCRIPTION OF SECURITY
1174 CERTIFICATION SCHEMES**

1175

1176 This annex describes in more detail how the security certification schemes in scope cover
1177 the elements enforcing trust as summarized in Table 1 and Table 2 in section 6.1.4.

1178

1179 **Table 1 - Enforcing trust in products**

1180

1181 Implementing security requirements that cover a threat analysis

1182 CC, CPA and CSPN cover this aspect of trust enforcement by requiring that the
1183 evaluator/certification body verifies the consistency of security requirements against a
1184 security problem definition. This means all schemes in scope demand that requirements are
1185 defined as countermeasures to specific threats.

1186

1187 ISO/IEC 19790 & 24759: Different security levels are defined, but it is unclear in which case /
1188 for which threats one should go for a specific security level. CC schemes are based on
1189 threats and assets; FIPS schemes are based on functionalities and security mechanisms

1190

1191 Product testing

1192 Product testing in the sense of security certification encompasses security functional testing
1193 (e.g. Test of user guidance - protection against misuse by purchaser) and vulnerability
1194 testing (e.g. penetration testing).

1195

1196 The four certification schemes fully cover security functional testing by requiring functional
1197 testing to be conducted and/or reviewed by the evaluator. There are some differences in how
1198 this is implemented in each certification scheme:

- 1199 - CC requires full functional testing by developer and sample testing by an evaluator
1200 while, depending on the evaluation level, the evaluator should also perform a full
1201 documentary review of the functional tests;
- 1202 - CSPN requires full functional testing by an evaluator
- 1203 - CPA requires full functional testing to be *witnessed or performed* by an evaluator
1204
- 1205 - ISO/IEC 19790 & 24759: much functional testing is performed (see ISO/IEC 24759)

1206

1207 CC, CPA and CSPN cover vulnerability testing by requiring evaluators to perform security
1208 testing based on available documentation. In CSPN the implementation (source code) is
1209 used for vulnerability and cryptographic assessment, when available. In CC and CPA it is
1210 only required to use the implementation for such test at higher assurance levels. Additionally,
1211 CC also requires the evaluator to review a security architecture documentation, which
1212 describes self-protection measures of the TOE and non-bypass ability of the security
1213 function. Furthermore at higher EAL's, CC requires that focused penetration testing is
1214 performed by the evaluator to assess the resistance to high profile attacks.

1215

1216 ISO/IEC 19790 & 24759: Vulnerability testing is not covered by these standards: ISO/IEC
1217 24759 describes conformance test for a cryptographic module against the functional and
1218 design requirements detailed in ISO/IEC 19790. The design requirements do contain
1219 Physical Security requirements (tamper evidence, detection, response), and higher security
1220 levels include mitigation requirements against attacks, but there is no penetration testing
1221 involved in the evaluation process.

1222

1223 Security measures for the premises of developers & OAM actors

SM-CG Sec073_DC

1224 Examples of such security measures are: organization of information security, human
1225 resources security, access control and asset management, etc.

1226 ISO/IEC 19790 & 24759: No measures are required for developers to secure their premises.

1227

1228 CC and CPA formally require that security measures are taken to protect the product in
1229 "confidentiality and integrity" during development. However, no method is provided to
1230 achieve those measures (developers for example rely on ISO 27001). CSPN includes this
1231 verification in the "developer interview" evaluation task, which is optional..

1232

1233 All four certification schemes require that user guidance is provided for evaluated products in
1234 order to secure the product during operation – administration and maintenance.

1235

1236 Use of proven methods and maintaining skills

1237 This aspect of trust in developers – OAM actors breaks down into several elements which
1238 are highlighted in **bold**.

1239

1240 CPA has strong requirements on **configuration management** (particularly focusing on
1241 automated configuration management and authorization) and **management of third party**
1242 **tools & components**, for example requiring that they are subject to the same configuration
1243 management requirements. CC also covers these elements; depending on the Evaluation
1244 Assurance Level, the requirements may be less strict than in CPA. CSPN includes this
1245 verification in the "developer interview" evaluation task, which is optional.

1246 ISO/IEC 19790 & 24759 design assurance is required as from security level 1. There are no
1247 requirements on third party tools.

1248

1249 CPA requires that **development teams are trained**, especially regarding flaw remediation
1250 process and secure coding and this must be assessed by the evaluator. CC suggests this
1251 verification as an example (in CEM) but does not require this verification formally. CSPN
1252 includes this verification in the "developer interview" evaluation task, which is optional.
1253 ISO/IEC 19790 & 24759 do not have such requirements.

1254

1255 CC, CPA and CSPN require that **user guidance** is provided to OAM-actors.

1256 ISO/IEC 19790 & 24759 requires an administration manual and a user manual

1257

SM-CG Sec073_DC

1258 Finally, Common Criteria require that developers and OAM-actors use proven methods
1259 covering additional aspects of quality assurance like:

- 1260 - A **documented lifecycle model** (formalization of product specification, design
1261 documentation, requirements traceability, etc.) providing for the necessary quality
1262 control over the development and maintenance of the product. This requirement is
1263 also covered by ISO/IEC 19790 which requires, depending on the security level,
1264 annotation to the source code and documentation, documentation of a final state
1265 model, etc. More generally, as in CC, assurance must be provided that the module is
1266 properly designed and developed.
- 1267 - A **flaw remediation procedure**, tracking (amongst others) product flaws, their
1268 effects, corrective measures, etc... This requirement is covered by Common Criteria
1269 and CPA.

1270 Committing to flaw remediation obligations, delays and information provision to end-users

1271 This aspect relates to information security incident management, including a patching policy.
1272 CPA heavily covers security flaw detection, correction and information and insists on
1273 verifying that flaw correction process is routinely followed in practice. CSPN has no formal
1274 requirement on this aspect of trust. ISO/IEC 19790 and 24759 do not have requirements
1275 regarding flaw remediation procedures.

1276
1277 Furthermore, CC and CPA require that timely action is taken for flaw remediation; CPA even
1278 defines service levels for customer information. CSPN at the other hand does not have
1279 formal requirements covering the above.

1280
1281 ISO/IEC 19790 & 24759 does not have such requirements.

1282 1283 **Table 2 - Enforcing trust in the scheme itself**

1284 1285 Recognition

1286 The certification schemes in scope are all, to some extent, nationally or internationally
1287 recognized. This recognition is achieved by:

- 1288 ○ The involvement of national authorities: The certification schemes in scope all
1289 have national governments involved in the creation, maintenance and
1290 endorsement of the scheme. In case of CC, national representatives signed
1291 the CC recognition agreement, while in case of CPA and CSPN the
1292 certification body itself is a national representative. ISO/IEC 19790 & 24759:
1293 the scheme will be delegated to national bodies. The profiling of the ISO/IEC

SM-CG Sec073_DC

1294 19790 standard will be tuned nationally. Today, there are ISO/IEC 19790
1295 certification bodies in Spain, Turkey, and Japan.
1296 ○ Being recognized as a standard: While CC is an international (ISO) standard,
1297 CPA and CSPN are both nationally recognized as a certification methodology.
1298 The ISO/IEC 19790 is an international standard. But there will be national
1299 certification bodies applying it.

1300

1301 Managing Certification Body accreditation

1302 All certification schemes in scope manage which organizations can be Certification Bodies
1303 (CB).

1304

1305 CC has put criteria in place for accreditation and revocation of individual Certification Bodies
1306 and for periodic assessment of individual Certification Bodies.

1307

1308 In case of CPA and CSPN this is less relevant since there is only one Certification Body
1309 which has ownership of the certification scheme. Nevertheless this aspect is considered to
1310 be fully covered by these schemes since it is clear to the market who is the CB.

1311

1312 ISO/IEC 19790 does not foresee accreditation of CBs. But there exist international
1313 accreditation bodies like ILAC that do it.

1314

1315 Information provision to stakeholders

1316 All certification schemes in scope cover this aspect by publishing the certificates obtained
1317 under the scheme on their website. The certificates can be accessed on-demand but only for
1318 products that have been evaluated with a request for international recognition.

1319

1320 Furthermore, the CC publishes information on accredited Certification Bodies; as mentioned
1321 in the previous section, this criterion is not relevant to CPA and CSPN.

1322

1323 ISO/IEC 19790 does not describe the publication of certificates. It will depend on each
1324 national CB.

1325

1326 Technological relevance of the methodology

1327 The methodology to come to security requirements and an evaluation process should be
1328 technologically relevant. This breaks down into several elements:

SM-CG Sec073_DC

- 1329
- 1330
- 1331
- 1332

- 1367
- The conceptual model may make use of CIA notions, is compatible with known risk analysis methods and known vulnerability quotation methods. This is the case for CC and CSPN which allow CIA to be used in the security problem definition, allow for risk formalization to be compatible with known methods and have a vulnerability potential table. In CPA security characteristics, there is no systematic security problem definition or vulnerability quotation. ISO/IEC 19790: CIA - Encryption of sensitive assets for I/O; SW & FW integrity; Availability is not covered. AAA: User authentication required from level 2; optional code authentication; Authorization is supported by Roles; Accounting is supported by security audit.
 - The scheme may facilitate coordination with technical communities to ensure technical relevance. CC and CPA involve technical communities by defining and using a process to request comments from the technical community on specific documents. CSPN does not actively involve the technical community, but is limited to domains (firewalls, data deletion, etc.) that are relevant by nature. ISO/IEC 19790 & 24759 does not have such requirements.
 - The scheme may cover generic security functionalities. Examples of such functionalities are: Security audit, logs, events & alarms; Role based access and account management; Disabled functions / interfaces; etc. CC and CSPN cover most of the elements as Security Functional Requirements (SFR's). However, some functionality like function disablement and authentication are not explicitly covered and require de creation of ad hoc SFR's. CPA at the other hand is focused on specific technologies and as such covers all security functionalities that are relevant for said technology. ISO/IEC 19790 & 24759: Crypto key management and role based authentication are covered; security audit is required from Level 2.
 - The scheme may cover patch management and firmware updates. CC, CPA and CSPN partially cover this by requiring maintenance evaluation for minor updates or full re-evaluation for major updates (although this is costly in case of regular updates). In CC, some national certification bodies performed R&D methods to certify patch mechanisms as security functions, in order to facilitate the certificate maintenance. ISO/IEC 19790 & 24759 do not contemplate the rules for re-certification in case of a change in the tested module. That would be part of the rules concerning the certification body. One can anticipate a retesting or regression testing proportional to the impact of the change in the compliance of 19790.
 - The scheme may support multiple security levels. CC supports several Evaluation Assurance Levels which correspond to different security levels. This means that advanced attacks are evaluated only if a high EAL is chosen which implies performing more thorough assurance verification. CPA and CSPN do not differentiate between security levels. ISO/IEC 19790 & 24759 define 4 security levels.

1368 Economics

1369 Next to being technologically relevant, the scheme can also be relevant in the business
1370 context in which it is designed to operate. This breaks down in several aspects:

- 1371 - The scheme may give the developer / user some means to manage to cost of
1372 certification or at least to give an up-front idea of what this cost can be.
 - 1373 o CC covers this by linking certification duration and complexity to the
1374 Evaluation Assurance Level (EAL). Furthermore, supporting documents
1375 approved for a specific domain can include duration indicators for certification.
 - 1376 o CSPN at the other hand commits to an evaluation duration of 8 weeks and a
1377 fixed number of working days. ANSSI can request certification requests if
1378 products are too complex to be evaluated under these conditions.
 - 1379 o CPA fixes the evaluation lab fees (currently 4000 GBP) but does not formally
1380 provide a means to manage certification duration.
 - 1381 o ISO/IEC 19790: not covered - there is no direct influence. It will depend on the
1382 CB and the lab.
- 1383 - The scheme may give an indication of duration and cost of certificate management
1384 and has procedures that limit this cost of such maintenance
 - 1385 o CC, CPA and CSPN are only applicable to a specific version of a product but
1386 do have an assurance continuity process. When a product is updated, an
1387 impact analysis has to be performed. When the impact of the update is
1388 considered minor, a simple maintenance report is published. When the impact
1389 is significant, re-certification is performed, but the evaluator makes maximum
1390 use of evidence collected in the previous certification.
 - 1391 o ISO/IEC 19790 and 24759 do not contemplate the rules for re-certification in
1392 case of a change in the tested module. That would be part of the rules
1393 concerning the certification body. One can anticipate a retesting or regression
1394 testing proportional to the impact of the change in the compliance of 19790.

1395 Scope

1396 CC: applies to a broad product range, going from access control to operation systems and
1397 smart meter gateways. Common Criteria is industry / product independent.

1398 CSPN: IT products can currently apply to CSPN if they belong to a specific list of domains.
1399 Only for products that can be tested in the pre-defined timing

1400 CPA covers only specified types of products/features of products.

1401 ISO/IEC 19790 and 24759: scope is broader than just a Security Module, but focusses on
1402 cryptographic functionalities.

1403
